**KEY POINTS**

Lifelong transfusion and chelation therapy significantly impacts quality of life for both patients with TDT and their caregivers.\(^1,2\)

Patients receiving allogeneic haematopoietic stem cell transplantation (HSCT) reported improved quality of life over patients receiving conventional transfusion/chelation therapy.\(^3\)

30-year overall survival (OS) in conventionally treated patients was similar to transplanted patients; however, transplanted patients reported higher mortality in the first ten years, with nearly 50% of the mortality being driven by acute GvHD.\(^4\)

**REFERENCES:**

*These health domains are evaluated as part of the Medical Outcomes Study Short Form 36-item (SF-36). They are defined as follows: Physical functioning covers role limitations due to physical health problems. The role-physical scale assesses the frequency of pain and interference of pain with usual roles. The general health scale measures individual perceptions of general health. The vitality scale assesses energy levels and fatigue. The social functioning scale measures the extent to which ill health interferes with social activities. The role-emotional scale assesses role limitations due to emotional problems. From: Busija L, Pausenberger E, Haines T, et al.
